## Instructions and Assumptions for Using Enterprise Budgets and Cost Calculators

### General Assumptions:

Since farming is inherently variable and constantly changing, we hope that this spreadsheet format will be helpful in adjusting these budgets to reflect your particular operation. Enterprise costs and returns vary from one location to the next and over time for any particular farming operation. Variability stems from differences in the following:

- Capital, labor, and natural resources
- Type and size of machinery complement
- Cultural practices
- Size of farm enterprise
- Crop yields
- Input prices
- Commodity prices
- Management skill

### Background and Specific Assumptions:

Economic costs are used in the University of Idaho costs and returns estimates. All resources are valued based on market price or opportunity cost. Input prices are based on the U of I's annual survey of agricultural supply companies. Except for contract crops, the selling price represents a forecast for 2016. The costs and returns estimates shown here are typical for growing grain and rotational crops in northern Idaho.

Production practices most closely represent those in Latah County. Production practices may be similar among individual farms, but each has a unique set of resources with varying levels of productivity and production problems, and therefore, slightly different costs. Farm size, crop rotation, age and type of equipment, soils, and quality of management are crucial factors that influence production costs.

### The Model Farm

This costs and returns estimate models a 2500-acre farm in a typical 3-year rotation of winter wheat followed by a spring grain and then a legume or another alternative to grain such as canola or mustard. In a typical year equal proportions would be devoted to each crop. Crop choices will vary by year, depending on relative crop prices and other management considerations. Returns for typical rotations are listed in Table 1 Summary of Returns by Crop and Rotation (\$/acre).

### Input Prices:

By entering input prices on the Input Prices sheet, all of the cost calculations will be automatically updated in the spreadsheet version of this report. Input cost changes can also be made on individual crop price sheets, over-riding the input cost formula on that particular crop budget. Input costs are based on a survey of input suppliers for each region.

### Crop Prices:

Crop prices can be adjusted on the Summary tab and the effects of this change will be reflected throughout all the budgets. (Yields can be adjusted similarly.) Crop prices are typically based on five-year average prices received by Idaho growers, with adjustments by region and for some contract crops.

### Machinery Costs:

Fixed and variable costs of machinery operation are calculated using a budget calculator program. Details on the machinery complement assumptions, usage, years of life, repair costs, fuel usage, etc., are available in the pdf file for each crop.

### Land Costs:

Land costs, included either as real or as opportunity costs, are based on a typical lease agreement for this area. While the owner-operator will not actually experience a land rental cost, this cost represents the minimum return owner-operators must receive to justify growing the crop themselves. To determine the profitability of crop production relative to other activities, the owner-operator may want to consider these forgone rental returns along with the usual production expenses.

A typical lease agreement in the areas surveyed is a one-third land owner and two-third tenant crop share, with the land owner paying land taxes, one-third of the fertilizer cost, one-third of the chemical cost, and one-third of the crop insurance. The tenant covers all other production expenses. This crop-share percentage can be adjusted in the crop worksheets. If the percentage is adjusted on the Summary tab, it is changed for all crops. If you want different crop-share percentages for different crops, adjust the percentage on the budget sheet for that crop. This valuable tool reveals how factors such as crop and input price increases as well as cropping choices affect revenue for landlords and operators differently. Note that pea, lentil, and garbanzo crop-share arrangements are typically 25/75.

### Labor Costs:

Labor rates include a base wage plus a percentage for Social Security, Medicare, unemployment insurance, and other labor overhead expenses. This rate can easily be changed on the Input Prices tab.

### Interest Costs:

Interest on operating capital is charged on total operating costs for six months for spring crops and for nine months for winter crops. The operating interest rate can be changed on the Input Prices sheet in the spreadsheet version of this bulletin. A general overhead charge of 5 percent of operating expenses is included to cover unallocated costs such as office expenses, phone service, legal and accounting fees, and utilities.

Please examine closely the assumptions we have used and make adjustments to reflect your particular operation. Adjustments in the variable costs can easily be made without affecting the overall accuracy of the budget information. Machinery costs are more difficult to adjust, due to the underlying complexity of machinery cost calculations. A separate machinery cost calculator program is used to develop the costs used in these budgets, which are based on specific machinery widths, tractor horsepower, type of operation, etc.

**Color Coding:**

A color coding system is used to indicate the source of the data for each budget and to show which data can be adjusted in the spreadsheet version of this report. Data in orange type can be changed without affecting the underlying equations in this cost calculator. Data with purple type are from the Summary sheet (Table 1). In the Summary sheet, crop price and yield have orange type. Adjusting any of those numbers will automatically update all calculations throughout the spreadsheet so you can quickly compare price and yield changes on net returns. Input prices can be easily updated by making changes in the green Input Prices sheet (Table 2). All calculations will again be updated throughout the spreadsheet. You will notice that data from the Input Prices tab appears in green ink on the Budget sheets.

**Acknowledgments:**

I wish to thank everyone who helped gather all of the information needed to create these worksheets. First and foremost, I thank the farmers who were willing to take the time to share their enterprise information in order to create this worksheet. Without their assistance we would not be able to provide this critical information to others. My colleagues at the University of Idaho, particularly Research Scientists Jim Davis and Traci Rauch, provided critical recommendations on herbicides, pesticides, and seeding rates. However, I take responsibility for any errors in these budgets. Please feel free to contact me with any comments or suggestions.

**Table 1. Summary of Returns by Crop and Rotation (\$/acre)**

By Crop:	Unit	Yield per acre	2016 Price (est.) per unit	Revenue per acre	Total Cost (TC) of Operation	Returns over TC (\$/acre)	Total Variable Costs (VC) (\$/acre)	Returns over VC (\$/acre)	Crop & Cost Share** Cost (\$/acre)	Percentage Share
Winter Wheat (WW)	bu	85	\$3.61	\$307	\$382	-\$75	\$262	\$45	\$56	67/33
